Normal cognitive performance for the population overlaps impaired performance of individuals

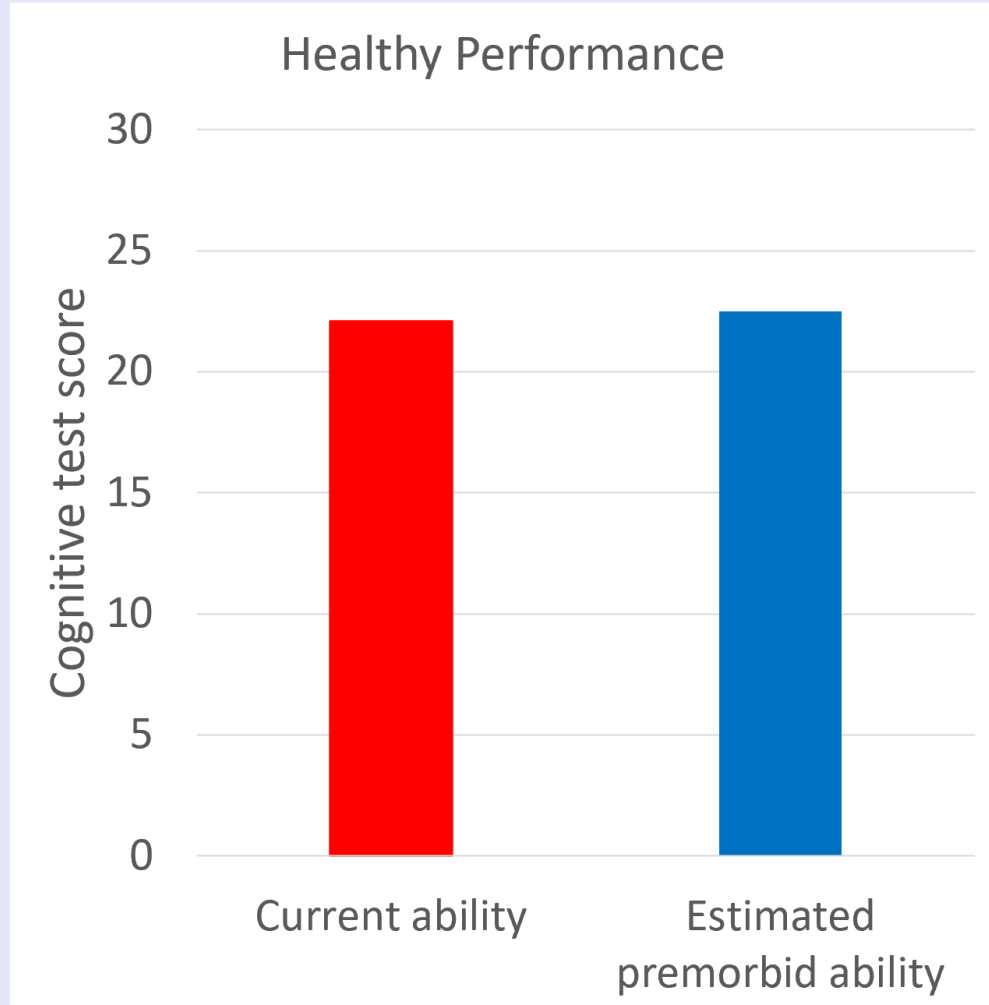

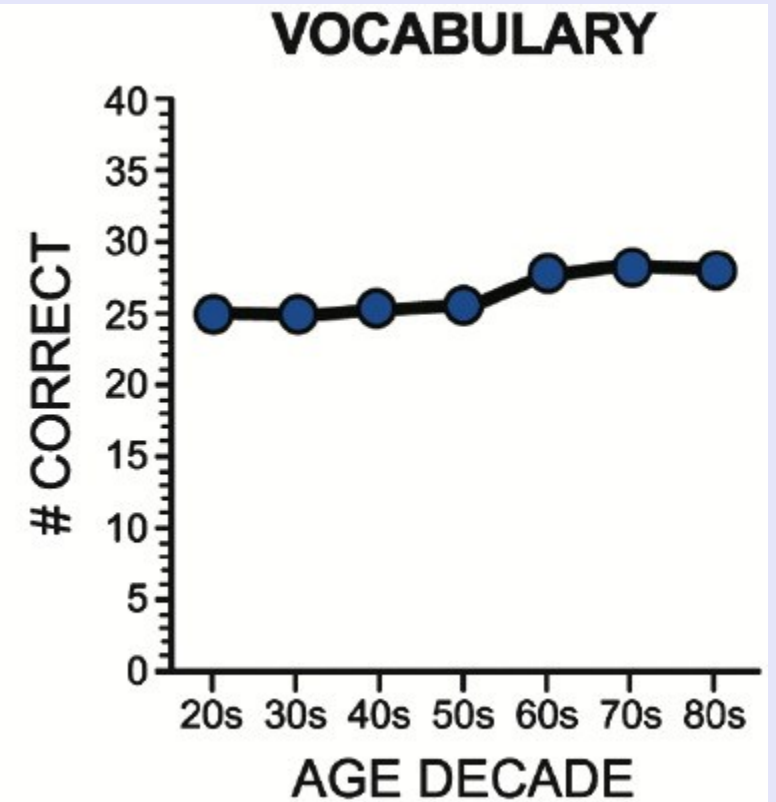

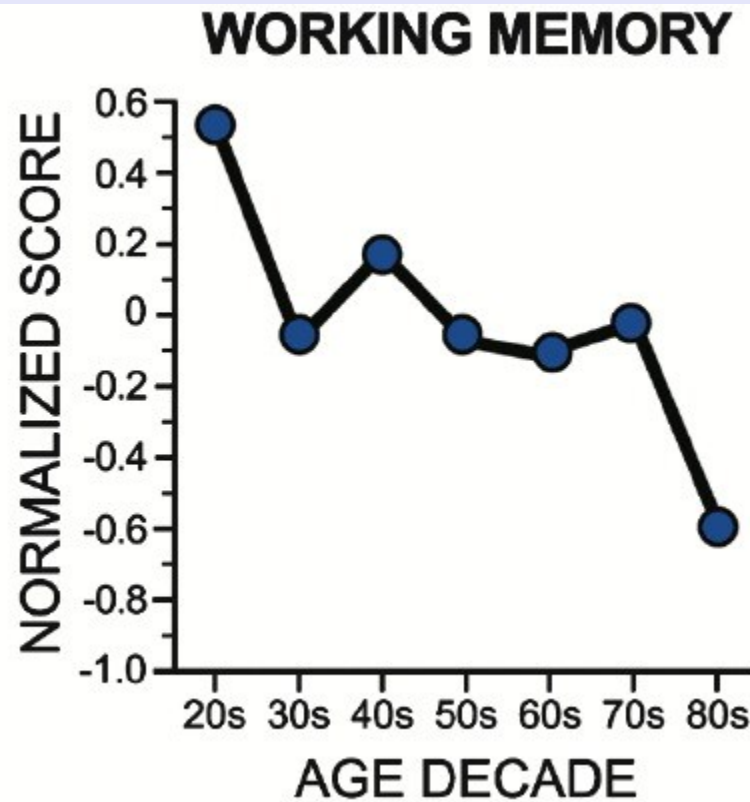

E.g. A patient with neurological illness could suffer a large drop in cognitive ability and still score 'normal'

Personalized cognitive assessment:

- If current ability is lower than estimated premorbid ability, this is evidence of acquired impairment

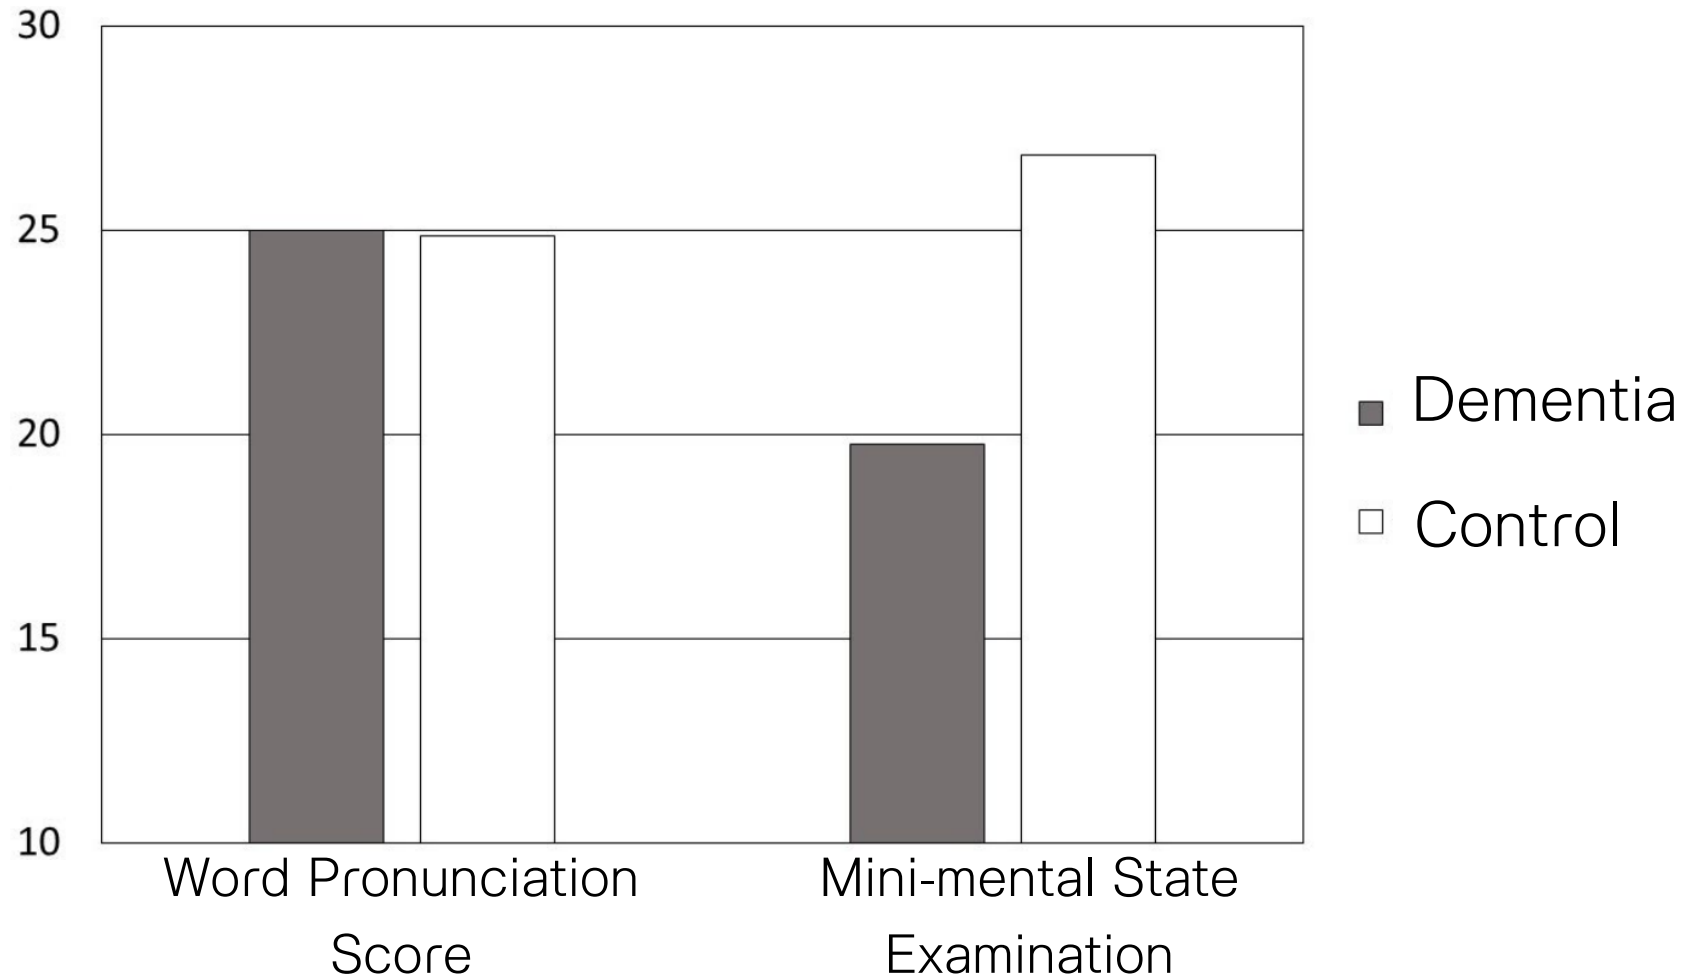

Buckner (2004). Memory and executive function in aging and AD: multiple factors that cause decline and reserve factors that compensate. *Neuron*, 44(1), 195-208.

Unlike most cognitive abilities, vocabulary does not decline with normal ageing (it actually increases)

Word knowledge has the highest overall association with other cognitive tests

Reading words through lexical routes is resistant to dementia

slank	—	chariot
lentil	—	glotex
stamen	—	dombus
loba	—	comet
pylon	—	stroin
scrapten	—	flannel

ราโนย	—	ภาพปักษ์
เขบ็ต	—	ปฏิวัลย์
จวัก	—	คเมช

Written Word

Speech

A cognitive model of speech production, adapted Gvion & Friedmann (2016). A principled relation between reading and naming in acquired and developmental anomia: Surface dyslexia following impairment in the phonological output lexicon. *Frontiers in Psychology*, 7.

N = 818 Thai adults: r = .20, p < .001

Item Reduction Using ML Techniques

- Why?
 - Increase efficiency - less time taken
 - Increase validity - less error, lower boredom and higher motivation
- Why not? (Maybe)
 - May affect replication of measurements within the instrument
 - May impact reliability
- Variance Inflation Factor (VIF)
 - Staffini et al 2022
 - Statistical Methods for Item Reduction in a Representative Lifestyle Questionnaire: Pilot Questionnaire Study, Staffini et al 2022.
 - Measure of collinearity (e.g. two items which always provide the same answer are not useful)
 - Remove items whose information is already represented by other items
- Automated iterative removal of items

Implementation and Outcomes of Automated VIF

- Steps:
 - Data cleaning - specify location (latitude/longitude), time taken, no. of goal items
 - Measure range for subcategories of sample (key classifiers: e.g. education, proficiency)
 - Loop for number of items to remove (actual - goal)
 - Calculate VIF
 - Remove item with highest VIF
 - Repeat
 - Check ranges for key classifiers and compare with original item list
- Reduction from 100 items to 50
- Range maintained for key classifiers
- Easy to set no. of goal items and reuse
- Can be easily applied to other multi-item questionnaires
- Further work
 - Comparison with/inclusion of other techniques for item reduction
 - User interface development
- Available online for download and use

Internal consistency (Cronbach's alpha)

Full 100 items $\alpha = .78$

VIF reduced $\alpha = .74$

Removed items $\alpha = .95$ (suggests low validity – attenuation paradox)

Association with self-report Thai language proficiency (ANOVA):

For 100 items eta-squared = .042

VIF reduced eta-squared = .046

Removed items eta-squared = .015

We are collecting data on a second sample, including standardized cognitive assessments of language skill, to assess the efficiency of the different subsets of items.

- Summary: we have developed a Thai lexical decision task that may be resistant to cognitive changes associated with ageing or disease.
- This research is ongoing, using data science methods to further refine the tool.

Special thanks to the research assistant:
